

Optimization Of Orthodontic Elastics Michel Langlade

This is Volume 7, and I have included the index here. Purpose: : The purpose of this report is to present the case of a 26-year-old female with a rare condition of skeletal dysplasia called Apert syndrome. This syndrome is characterized by the following features: short stature, high arched palate, simian lines, brachycephaly, hypertelorism, high-arched narrow palpebral fissures, epicanthal folds, prominent ear, micrognathia, short neck, short neck, and wide mouth. Also known as Apert's syndrome, the prognosis of this condition is poor due to the high rate of mortality and morbidity that comes from the characteristic features of this syndrome. This report will present the patient's case and how the diagnosis was made and subsequently how treatment was provided. Materials and Methods: : The patient is a 26-year-old Caucasian female who is the daughter of a second-cousin union. The patient was referred to the oral and maxillofacial surgery division due to a nonhealing split palmaris longus tendon which caused a pinching sensation in the right thenar eminence. On clinical examination, the patient had no labial eruption or any signs of periodontal disease. The patient was given two sets of intraoral elastic bands to facilitate the split palmaris longus tendon healing. The banding was accomplished using the T-Tang band. Subsequently, the patient presented to the oral and maxillofacial surgery clinic five months after treatment. The patient is currently wearing nonrigid retractor arch wire for orthodontic correction. Results and Discussion: : The Apert syndrome is characterized by the presence of 11 major and minor facial anomalies. This syndrome presents a large number of dental anomalies such as agenesis, developmental anomalies, and hypodontia. These anomalies are more common in people with Apert syndrome. This case report will discuss the significance of early diagnosis and management. The management of this patient included orthodontic treatment to align the malocclusion and avoid malocclusion-induced sequelae that are associated with an uncoordinated masticatory system and damage to the dentition. Conclusions: : Although this is a rare syndrome, dentists should be aware of it so they can better identify and treat dental problems that may be associated with it. OBJECTIVE: : The purpose of this paper is to describe
